

## HETEROCYCLIC COMPOUNDS AND THEIR USE AS ANTICANCER AGENTS

### Field of the Invention

The present invention encompasses heterocyclic compounds and derivatives thereof, pharmaceutical compositions containing the compounds, methods for making the compounds, and methods of treating cancer and/or ocular diseases by administering a therapeutically effective amount of the compounds to subjects in need of such treatment.

### Background of the Invention

Malignant tumors, characterized by abnormal proliferation of neoplastic cells, are one of the most common diseases worldwide, and the subset of human cancer types amenable to curative treatment is rather small. Although there is tremendous progress in understanding the molecular events that lead to malignancy, there is still a high demand for the development of clinically innovative drugs that can effectively inhibit proliferation of cancer cells and cure human cancer.

Taxol is one of many antitumor agent developed in the past three decades, effective for treatment of ovarian and breast cancers, with a worldwide sale of USD 1.5 billion in 2002. Because taxol halts proliferation of cancer cells by acting on microtubules, taxol's success as a chemotherapeutic agent brought the focus back to the potential of microtubules as a potential target.

Microtubules are elements of the cell cytoskeleton that play a key role in cell division, shape and motility, as well as intracellular transport. Microtubules are highly dynamic structures formed by heterodimers of alpha and beta tubulin that assemble into polymers in a GTP-dependent manner. During cell division microtubules disassemble into soluble tubulin dimers, prior to their reassembly and formation of the mitotic spindle, a structure that provides segregation of replicated chromosomes to daughter cells. For proper cell division to occur, it is essential that microtubules are able to polymerize and depolymerize. Microtubules in the mitotic spindle are more dynamic than those in non-dividing cells, and thus can be targeted by agents that affect microtubule dynamics. By altering microtubule polymerization/ depolymerization these agents affect mitotic spindle function, arrest dividing cells in the G2/M phase of the cell cycle, and ultimately lead to apoptotic cell death. As neoplastic cells have high proliferation rates, they can be targeted by these antimitotic agents. Compounds that bind to tubulin, interfere with

microtubule dynamics and inhibit division of cancer cells and are indeed some of the most effective cancer therapeutic agents in use.

Clinically available compounds, such as taxol or vincristine, have been known to have disadvantages, such as, (1) high toxicity, (2) marginal bioavailability and poor solubility, (3) complex synthesis or isolation procedures, and (4) development of drug resistance in patients. Therefore, synthetic low molecular weight compounds with oral  
5 bioavailability and high therapeutic index for first and second line therapy are desirable.

Because of their clinical potential, several synthetic molecules that bind to tubulin are currently being evaluated in preclinical or early clinical stage. Most notably, WO  
10 01/22954, assigned to Asta Medica, discloses indole-3-glyoxylamide derivatives with antitumor activity. One compound, D-24851, has been shown to exert antitumor activity *in vivo*, shows efficacy toward MDR cells and lacks neurotoxicity. See, Cancer Research 61, 392, 2001. DE 10020852, assigned to Asta Medica, discloses 1H-indol-2-yl aryl ketones and related compounds as antitumor agents. Specifically, D64131 has been  
15 shown to be orally active, efficacious in xenograft models and showed no signs of toxicity. See, Cancer Research 62, 3113, 2002. South African publication ZA 2000000419, assigned to Abbott, discloses oxadiazoline derivatives as antiproliferative agents. A-204197 has shown to be effective against Taxol resistant cell lines. See, Cancer Research 61, 5480, 2001. U.S. patent 6,521,658, also assigned to Abbott,  
20 discloses certain sulfonamides as cell proliferation inhibitors. WO 02/39958, assigned to Tularik, discloses combination therapy using pentafluorobenzenesulfonamides and antineoplastic agents.

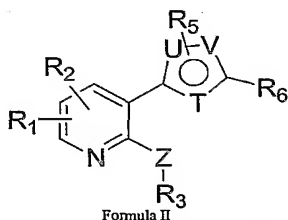

Besides their antitumorigenic effect by inhibition of proliferation of tumor cells, tubulin agents can also act as vascular disrupting agents (VDAs). The effect of tubulin  
25 agents on tumor endothelial cells may cause in a single dose the selective shutdown of tumor vasculature, depriving tumor cells of nutrients and oxygen, and causing tumor necrosis. See, *Clin. Cancer Res.*, 10:415-27 (2004) or *Cancer*, 100:2491-9 (2004). Preclinical data have shown that some but not all tubulin small molecules have antivasular and antiangiogenic activities. While marketed drugs such as paclitaxel and  
30 vinblastine might have antiangiogenic actions in low doses, they only have vascular disrupting effects at maximum tolerated doses (MTD). Second generation small molecule tubulin agents such as combretastatin and its analogues, nevertheless, are effective at doses much lower than MTD. Combretastatin A-4 phosphate has been shown to change endothelial cell morphology, shut down tumor vasculature, and induce tumor necrosis in

mouse tumor models. *See, Cancer Research*, 59, 1626 (1999). Tubulin agents have shown to have synergistic anticancer effect with existing therapies. *See, Cancer Research*, 59, 1626 (1999); *Eur. J. Cancer*, 40:284-90 (2004); *Anticancer Res.* 23:1619-23 (2003). Antivascular and anti-angiogenic actions of small molecule tubulin binding agents have also been demonstrated in clinical trials. *See, Cancer Res.* 63:1144-7 (2003); *Clin. Cancer Res.* 10:415-27 (2004). Tubulin small molecules VDAs additionally can be useful in the treatment of ocular diseases in which retinal neovascularization is pathological, such as age-dependent macular degeneration and diabetic retinopathy. *See, Oncogene*, 22: 6537-6548 (2003).

The desirability for novel and active compounds that may treat diseases associated with effects upon microtubules are of great interest as novel therapeutics.

Other factors, more practical in nature, which those skilled in the art may take into account in the selection include the cost of the raw materials, ease of crystallization, yield, stability, solubility, hygroscopicity and flowability of the resulting bulk drug. Pharmaceutically acceptable salts may be prepared by the addition of an appropriate acid. Thus, the compound can be used in the form of salts derived from inorganic or organic acids. Examples include, but are not limited to, acetate, adipate, alginate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camphorsulfonate, digluconate, dodecylsulfate, ethanesulfonate, fumarate, glucoheptanoate, glycerophosphate, hemisulfate, heptanoate, hexanoate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxy-ethanesulfonate, lactate, maleate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, pamoate, pectinate, persulfate, 3-phenylpropionate, pivalate, propionate, succinate, tartrate, or undecanoate.

As used herein, the term “subject” refers to a mammal, preferably a human, but can also be an animal in need of veterinary treatment.

When a compound of the present invention is present as a salt or hydrate that is non-pharmaceutically acceptable, that compound can be converted under certain circumstances to a salt or hydrate form that is pharmaceutically acceptable in accordance with the present invention.

When the compound is negatively charged, it is balanced by a counterion, such as, an alkali metal cation such as sodium or potassium. Other suitable counterions include calcium, magnesium, zinc, ammonium, or alkylammonium cations, such as tetramethylammonium, tetrabutylammonium, choline, triethylhydroammonium, meglumine, triethanol-hydroammonium, and the like. An appropriate number of counterions are associated with the molecule to maintain overall charge neutrality. Likewise, when the compound is positively charged, *e.g.*, protonated, an appropriate number of negatively charged counterions are present to maintain overall charge neutrality. These pharmaceutically acceptable salts are within the scope of the present invention.

Also included in the present invention are pharmaceutically acceptable salts of the compounds described within. Compounds disclosed herein which possess a sufficiently

acidic functional group, a sufficiently basic functional group, or both, and accordingly can react with any of a number of organic or inorganic bases, or organic or inorganic acids, may form a salt. Acids commonly employed to form acid addition salts from compounds with basic groups are inorganic acids including, but are not limited to,

5 hydrochloric acid, hydrobromic acid, hydroiodic acid, sulfuric acid, or phosphoric acid, and organic acids including, but are not limited to, para-toluenesulfonic acid, methanesulfonic acid, oxalic acid, para-bromophenyl-sulfonic acid, carbonic acid, succinic acid, citric acid, benzoic acid, or acetic acid. Examples of such salts include, but are not limited to, the sulfate, pyrosulfate, bisulfate, sulfite, bisulfite, phosphate,

10 monohydrogenphosphate, dihydrogenphosphate, metaphosphate, pyrophosphate, chloride, bromide, iodide, acetate, propionate, decanoate, caprylate, acrylate, formate, isobutyrate, caproate, heptanoate, propionate, oxalate, malonate, succinate, suberate, sebacate, fumarate, maleate, butyne-1,4-dioate, hexyne-1,6-dioate, benzoate, chlorobenzoate, methylbenzoate, dinitrobenzoate, hydroxybenzoate, methoxybenzoate,

15 phthalate, sulfonate, xylenesulfonate, phenylacetate, phenylpropionate, phenylbutyrate, citrate, lactate, gamma-hydroxybutyrate, glycolate, tartrate, methanesulfonate, propanesulfonate, naphthalene-1-sulfonate, naphthalene-2-sulfonate, mandelate, and the like.

If the compound has an acidic proton, a salt may be formed by the addition of

20 base to form a pharmaceutically acceptable base addition salt. Base salts include, but are not limited to, ammonium salts, alkali metal salts, alkaline earth metal, salts with organic bases, and salts with amino acids. Alkali metal salts include, but are not limited to, sodium or potassium salts; alkaline earth metal salts include, but are not limited to, calcium and magnesium salts; salts with organic bases include, but are not limited to,

25 dicyclohexylamine salts, N-methyl-D-glucamine; and salts with amino acids include, but are not limited to, arginine, lysine, and the like.

The basic nitrogen-containing groups may be quaternized with agents such as lower alkyl halides, including, not limited to, methyl, ethyl, propyl, or butyl chloride, bromide, or iodide; dialkyl sulfates including, not limited to, dimethyl, diethyl, or dibutyl;

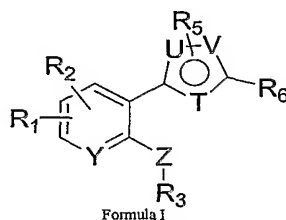

30 and diamyl sulfates, long chain halides including, not limited to, decyl, lauryl, myristyl, or stearyl chlorides, bromides, or iodides; or aralkyl halides including, but not limited to, benzyl and phenethyl bromides and the like.

The presence of pharmaceutically acceptable salts within the scope of the present compounds is not intended to limit the compounds of the present invention to those that

are synthetically prepared. The compounds of the present invention also include compounds that are converted within the body and prodrugs. As used herein, term “pro-drug” refers to a form of the compound of the present invention suitable for administration to a patient without undue toxicity, irritation, allergic response, and the like, and effective for their intended use. A pro-drug is transformed *in vivo* to yield the parent compound of the Formula I herein, for example by hydrolysis in blood. A thorough discussion is provided in T. Higuchi and V. Stella, *Pro-drugs as Novel Delivery Systems* Vol. 14 of the A. C. S. Symposium Series, and in Edward B. Roche, ed., *Bioreversible Carriers in Drug Design*, American Pharmaceutical Association and Pergamon Press, 1987.

The compounds of the present invention may have asymmetric centers and occur as racemates, mixtures of diastereomers, enantiomerically enhanced mixtures, or as individual enantiomers. All isomeric forms and/or polymorphs are included in the present invention.

Even most preferably, the compounds of the invention encompass compounds of Formulas IIA, IIB, IIC, IIIA, IIIB, or IIIC, wherein Z is NH.

Compounds of Formula I may be made using a variety of synthetic pathways. For illustration purposes, applicants provide the following synthetic schemes, with the understanding that one skilled in the art may vary conditions and/or reagents without deviating from the described process.

20 Compounds of Formula I wherein the five membered ring is a triazole are made using the synthetic pathways illustrated in Schemes 1 and 2. Although the schemes illustrate a six membered ring with one substitution, a second substitution is well within the abilities of the ordinary skilled artisan. The reactions may be carried out consecutively, *i.e.*, with intervening isolation and/or purification steps, or concurrently, *i.e.*, the reaction mixture is carried forth in the reaction sequence without isolation and/or purification.

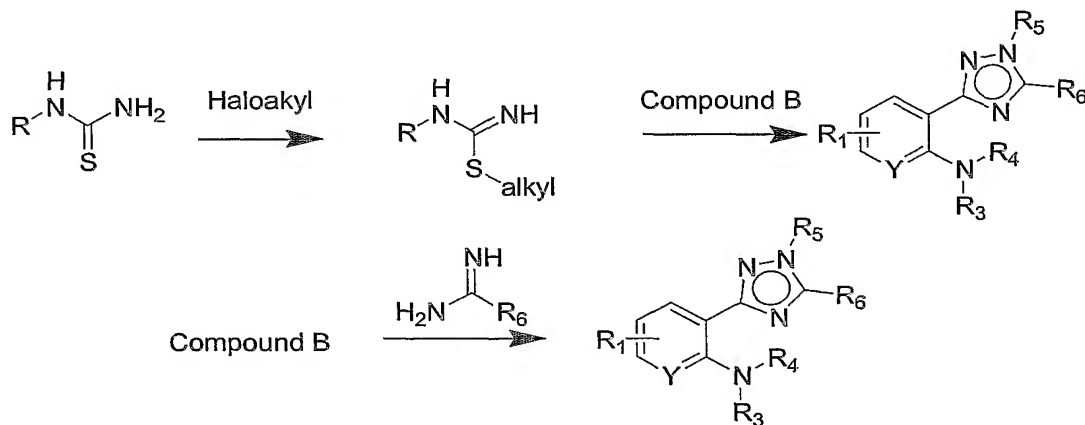

Compound A may be synthesized in at least two ways as illustrated by Scheme 1. In one case, the ester of 2-halobenzoate or 2-halonicotinate is reacted with a mono or disubstituted amine under basic conditions to form Compound A. An alternative, is to react an ester of 2-aminonicotinoate or 2-aminobenzoate, as illustrated a methyl ester, with a substituted aldehyde and a reducing agent, such as NaBH(OAc)<sub>3</sub>, to yield Compound A. Thereafter, Compound A is reacted with a substituted hydrazine to yield Compound B.

Scheme 1

In a second sequence, a halomethane is allowed to react with a substituted thiourea which is then allowed to react with Compound B to yield compounds of Formula II, wherein the five-membered ring is a substituted or unsubstituted triazole. See Scheme 2.

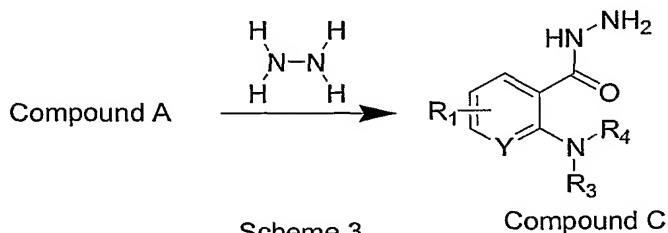

5 2. As the skilled artisan easily recognizes, the triazole may be substituted by using a substituted hydrazine or N,N'-disubstituted thiourea. In an alternative reaction sequence, Compound B is allowed to react with an amidine to form compounds of Formula I wherein the five-membered ring is a triazole.

Scheme 2

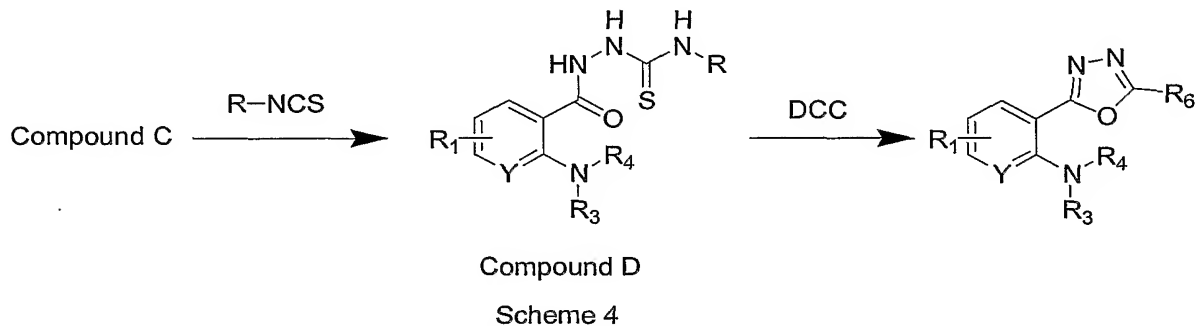

Compounds of Formula I wherein the five-membered ring is an oxadiazole are made using the synthetic pathways illustrated in Schemes 3 and 4. Compound A,

10 synthesized as described above, is allowed to react with hydrazine to form Compound C.

Scheme 3

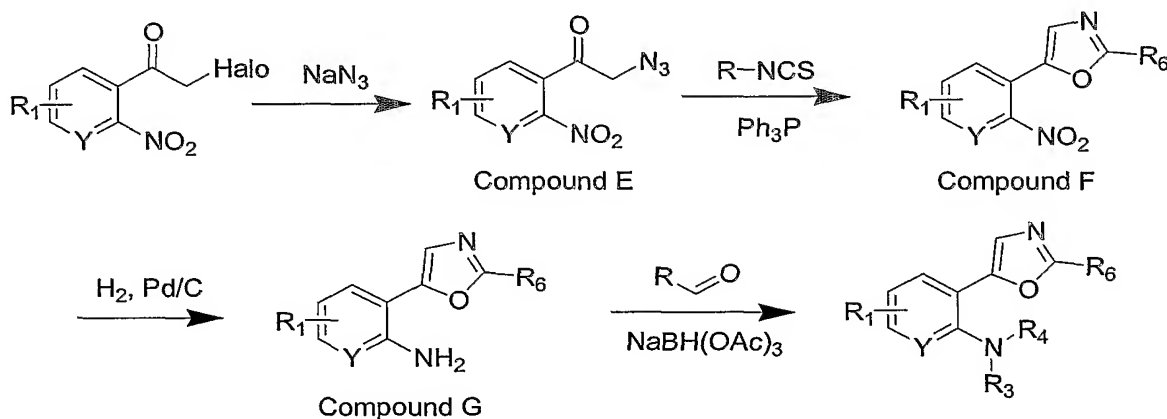

Thereafter, Compound C is allowed to react with an isothiocyanate to yield Compound D. Subsequently, Compound D is allowed to react with a coupling reagent, such as DCC, to yield compounds of Formula I, wherein the five-membered ring is an oxadiazole ring. See Scheme 4.

5

Compounds wherein the five-membered ring is an oxazole are made using the synthetic pathways illustrated in Scheme 5. In one case, a substitution reaction of an 2-halo-2'-nitroacetophenone with an azide to form Compound E, which is then allowed to react with an isothiocyanate to form Compound F. Hydrogenation of the nitro group into an amine (Compound G), followed by reaction with an aldehyde yields compounds of Formula I, wherein the five-membered ring is an oxazole.

The pharmaceutical compositions of the invention comprise compounds of Formula I, or a pharmaceutically acceptable salt, solvate, hydrate, or clathrate thereof as an active ingredient, and may also contain a pharmaceutically acceptable carrier and optionally other therapeutic ingredients known to those skilled in the art. Preferred pharmaceutical compositions comprise at least one compound of Formula IIA, IIB, IIC, IIIA, IIIB, or IIIC.

15

Another aspect of the present invention relates to pharmaceutical compositions, which include at least one compound of the present invention as described herein (that is, a compound of Formula I) or a pharmaceutically acceptable salt, hydrate or pro-drug thereof, in combination with a pharmaceutically acceptable carrier.

5 Compositions of the invention are suitable for oral, mucosal (*e.g.*, nasal, vaginal, or rectal), parenteral (*e.g.*, subcutaneous, intravenous, bolus injection, intramuscular, or intraarterial), sublingual, transdermal, or buccal administration, although the most suitable route in any given case will depend on the nature and severity of the condition being treated. The compositions may be conveniently presented in unit dosage form and  
10 prepared by any of the methods well known in the part of pharmacy. Dosage forms include tablets, caplets, troches, lozenges, dispersions, suspensions, suppositories, solutions, capsules, soft elastic gelatin capsules, patches, and the like. Preferred dosage forms are those suitable for oral administration.

The compositions of the present invention may be employed in solid or liquid  
15 form including for example, powder or crystalline form, in solution or in suspension. The choice of carrier and the content of active compound in the carrier are generally determined in accordance with the solubility and chemical properties of the desired product, the particular mode of administration and the provisions to be observed in pharmaceutical practice. Thus, the carrier employed may be, for example, either a solid  
20 or liquid.

One method of administering a solid dosage form is to form solid compositions for rectal administration, which include suppositories formulated in accordance with known methods and containing at least one compound of the present invention. Examples of solid carriers include lactose, sucrose, talc, gelatin, agar, pectin, acacia,  
25 magnesium stearate, stearic acid and the like.

Examples of liquid carriers include syrup, peanut oil, olive oil, water and the like. For parenteral administration, emulsions, suspensions or solutions of the compounds according to the invention in vegetable oil, for example sesame oil, groundnut oil or olive oil, or aqueous-organic solutions such as water and propylene glycol, injectable organic  
30 esters such as ethyl oleate, as well as sterile aqueous solutions of the pharmaceutically acceptable salts, are used. Injectable forms must be fluid to the extent they can be easily syringed, and proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prolonged absorption of the injectable compositions can be

brought about by use of agents delaying absorption, for example, aluminum monostearate and gelatin.

The solutions of the salts of the products according to the invention are especially useful for administration by intramuscular or subcutaneous injection. Solutions of the active compound as a free base or pharmacologically acceptable salt can be prepared in water suitably mixed with a surfactant such as hydroxypropyl-cellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, and mixtures thereof and in oils. The aqueous solutions, also including solutions of the salts in pure distilled water, may be used for intravenous administration with the proviso that their pH is suitably adjusted, that they are judiciously buffered and rendered isotonic with a sufficient quantity of glucose or sodium chloride and that they are sterilized by heating, irradiation, microfiltration, and/or by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal, and the like.

Examples of injectable dosage forms include sterile injectable liquids, *e.g.*, solutions, emulsions and suspensions. Sterile injectable solutions are prepared by incorporating the active compound in the required amount in the appropriate solvent with various of the other ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the various sterilized active ingredient into a sterile vehicle which contains the basic dispersion medium and the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, methods of preparation may include vacuum drying and a freeze-dry technique that yields a powder of the active ingredient plus any additional desired ingredient from previously sterile-filtered solution thereof.

Examples of injectable solids include powders that are reconstituted, dissolved, or suspended in a liquid prior to injection. In injectable compositions, the carrier typically includes sterile water, saline or another injectable liquid, *e.g.*, peanut oil for intramuscular injections. Also, various buffering agents, preservatives and the like can be included within the compositions of the present invention.

For oral administration, the active compound may be administered, for example, with an inert diluent or with an assimilable edible carrier, or it may be enclosed in hard or soft shell gelatin capsules, or it may be compressed into tablets, or it may be incorporated directly with the food of the diet, or may be incorporated with excipient and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups,

wafers, and the like. Examples of oral solid dosage forms include tablets, capsules, troches, lozenges and the like. Examples of oral liquid dosage forms include solutions, suspensions, syrups, emulsions, soft gelatin capsules and the like. Carriers for oral use (solid or liquid) may include time delay materials known in the art, such as glyceryl monostearate or glyceryl distearate alone or with a wax. To prepare a capsule, it may be advantageous to use lactose and liquid carrier, such as high molecular weight polyethylene glycols.

Topical administration, in the form of gels (water or alcohol based), creams or ointments, for example, containing compounds of the invention may be used. Topical applications may be formulated in carriers such as hydrophobic or hydrophilic bases to form ointments, creams, lotions, in aqueous, oleaginous or alcoholic liquids to form paints or in dry diluents to form powders. Such topical formulations can be used for example, to treat ocular diseases as well as inflammatory diseases such as rheumatoid arthritis, psoriasis, contact dermatitis, delayed hypersensitivity reactions and the like.

Compounds of the invention may be also incorporated in a gel or matrix base for application in a patch, which would allow a controlled release of compound through transdermal barrier.

For administration by inhalation, compounds of the invention may be dissolved or suspended in a suitable carrier for use in a nebulizer or a suspension or solution aerosol, or may be absorbed or adsorbed onto a suitable solid carrier for use in a dry powder inhaler.

Compositions according to the invention may also be formulated in a manner that resists rapid clearance from the vascular (arterial or venous) wall by convection and/or diffusion, thereby increasing the residence time of the viral particles at the desired site of action. A periadventitial depot comprising a compound according to the invention may be used for sustained release. One such useful depot for administering a compound according to the invention may be a copolymer matrix, such as ethylene-vinyl acetate, or a polyvinyl alcohol gel surrounded by a Silastic shell. Alternatively, a compound according to the invention may be delivered locally from a silicone polymer implanted in the adventitia.

An alternative approach for minimizing washout of a compound according to the invention during percutaneous, transvascular delivery comprises the use of nondiffusible, drug-eluting microparticles. The microparticles may be included a variety of synthetic polymers, such as polylactide for example, or natural substances, including proteins or

polysaccharides. Such microparticles enable strategic manipulation of variables including total dose of drug and kinetics of its release. Microparticles can be injected efficiently into the arterial or venous wall through a porous balloon catheter or a balloon over stent, and are retained in the vascular wall and the periadventitial tissue for at least about two weeks. Formulations and methodologies for local, intravascular site-specific delivery of therapeutic agents are discussed in Reissen et al. (*J. Am. Coll. Cardiol.*, 23: 1234-1244 (1994)).

A composition according to the invention may also comprise a hydrogel which is prepared from any biocompatible or non-cytotoxic (homo or hetero) polymer, such as a hydrophilic polyacrylic acid polymer that can act as a drug absorbing sponge. Such polymers have been described, for example, in application WO93/08845. Certain of them, such as, in particular, those obtained from ethylene and/or propylene oxide are commercially available.

Another embodiment of the invention provides for a compound according to the invention to be administered by means of perfusion balloons. These perfusion balloons, which make it possible to maintain a blood flow and thus to decrease the risks of ischaemia of the myocardium, on inflation of the balloon, also enable the compound to be delivered locally at normal pressure for a relatively long time, more than twenty minutes, which may be necessary for its optimal action.

Alternatively, a channeled balloon catheter (such as "channeled balloon angioplasty catheter", Mansfield Medical, Boston Scientific Corp., Watertown, Mass.) may be used. This catheter includes a conventional balloon covered with a layer of 24 perforated channels that are perfused via an independent lumen through an additional infusion orifice. Various types of balloon catheters, such as double balloon, porous balloon, microporous balloon, channel balloon, balloon over stent and hydrogel catheters, all of which may be used to practice the invention, are disclosed in Reissen *et al.* (1994).

Another aspect of the present invention relates to a pharmaceutical composition including a compound according to the invention and poloxamer, such as Poloxamer 407, which is a non-toxic, biocompatible polyol, commercially available (*e.g.*, from BASF, Parsippany, N.J.). A poloxamer impregnated with a compound according to the invention may be deposited for example, directly on the surface of the tissue to be treated, for example during a surgical intervention. Poloxamer possesses essentially the same advantages as hydrogel while having a lower viscosity. The use of a channel balloon catheter with a poloxamer impregnated with a compound according to the invention may

be advantageous in that it may keep the balloon inflated for a longer period of time, while retaining the properties of facilitated sliding, and of site-specificity of the poloxamer.

The composition may also be administered to a patient via a stent device. In this embodiment, the composition is a polymeric material in which the compound of the invention is incorporated, which composition is applied to at least one surface of the stent device.

Polymeric materials suitable for incorporating the compound of the invention include polymers having relatively low processing temperatures such as polycaprolactone, poly(ethylene-co-vinyl acetate) or poly(vinyl acetate or silicone gum rubber and polymers having similar relatively low processing temperatures. Other suitable polymers include non-degradable polymers capable of carrying and delivering therapeutic drugs such as latexes, urethanes, polysiloxanes, styrene-ethylene/butylene-styrene block copolymers (SEBS) and biodegradable, bioabsorbable polymers capable of carrying and delivering therapeutic drugs, such as poly-DL-lactic acid (DL-PLA), and poly-L-lactic acid (L-PLA), polyorthoesters, polyiminocarbonates, aliphatic polycarbonates, and polyphosphazenes.

In addition to the active compound and the pharmaceutically acceptable carrier, the compositions of the present invention optionally contain one or more excipients that are conventional in the art. For example, excipients such as lactose, sodium citrate, calcium carbonate, dicalcium phosphate and disintegrating agents such as starch, alginic acids and certain complex silica gels combined with lubricants such as magnesium stearate, sodium lauryl sulfate and talc may be used for preparing tablets, troches, pills, capsules and the like.

Various other materials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets, pills, or capsules may be coated with shellac, sugar or both. When aqueous suspensions are used they may contain emulsifying agents or agents which facilitate suspension. Diluents such as sucrose, ethanol, polyols such as polyethylene glycol, propylene glycol and glycerol, and chloroform or mixtures thereof may also be used. In addition, the active compound may be incorporated into sustained-release preparations and formulations.

The percentage of active ingredient in the compositions of the invention may be varied. Several unit dosage forms may be administered at about the same time. A suitable dose employed may be determined by a physician or qualified medical professional, and depends upon various factors including the desired therapeutic effect,

the nature of the illness being treated, the route of administration, the duration of the treatment, and the condition of the patient, such as age, weight, general state of health and other characteristics, which can influence the efficacy of the compound according to the invention. In adults, doses are generally from about 0.001 to about 50, preferably about 5 0.001 to about 5, mg/kg body weight per day by inhalation; from about 0.01 to about 100, preferably 0.1 to 70, more preferably 0.5 to 10, mg/kg body weight per day by oral administration; from about 0.1 to about 150 mg applied externally; and from about 0.001 to about 10, preferably 0.01 to 10, mg/kg body weight per day by intravenous or intramuscular administration.

10 The compounds and compositions according to the invention may be administered as frequently as necessary as determined by a skilled practitioner in order to obtain the desired therapeutic effect. Some patients may respond rapidly to a higher or lower dose and may find much weaker maintenance doses adequate. For other patients, it may be necessary to have long-term treatments at the rate of 1 to 4 doses per day, in accordance 15 with the physiological requirements of each particular patient. Generally, the active product may be administered orally 1 to 4 times per day. For other patients, it may be necessary to prescribe not more than one or two doses per day.

The compounds of the present invention may also be formulated for use in conjunction with other therapeutically active compounds or in connection with the 20 application of therapeutic techniques to address pharmacological conditions, which may be ameliorated through the application of a compound according to the present invention.

One embodiment of the invention encompasses method of treating cancer using the compounds of the invention. The disclosed compounds can be used to treat subjects with cancer, including multi-drug resistant cancers. A cancer is resistant to a drug when 25 it resumes a normal rate of tumor growth while undergoing treatment with the drug after the tumor had initially responded to the drug. The term "multi-drug resistant cancer" refers to cancer that is resistant to two or more drugs, typically five or more.

The disclosed compounds can be co-administered with other anticancer agents such as Taxol, Vincristine, Adriamycin, Etoposide, Doxorubicin, Dactinomycin, 30 Mitomycin C, Bleomycin, Vinblastine, Cisplatin, Erbitux, Avastin, Irressa, and the like. Additionally, the disclosed compounds can be co-administered with bioactive anticancer agents such as kinase inhibitors, kinase receptors, antigenesis inhibitors, cell cycle inhibitors, cytotoxic targeting agents, signal transduction pathway inhibitors, and the like.

The method can also be carried in combination with other cancer treatments such as surgery, radiation, and the like.

Moreover, the compounds of Formula I may be used for *in vivo* and *in vitro* investigative, diagnostic, or prophylactic methods, which are well known in the art.

5       The methods of the present invention encompass administration of a therapeutically effective amount of at least one compound of Formula I to a mammal in need of such treatment. As used herein, the term "administering" means delivering the compounds of the present invention to a mammal by any method that may achieve the result sought. The method may be, for example, orally, parenterally (intravenously or  
10       intramuscularly), topically, transdermally, or by inhalation. The term "mammal" as used herein is intended to include, but is not limited to, humans, laboratory animals, domestic pets and farm animals. The term "therapeutically effective amount" as used herein with respect to the treatment or prevention of cancer encompasses an amount of compound of the present invention that when administered to a mammal is effective in producing the  
15       desired therapeutic effect. For example, a desired effect is a tumor growth rate reduction to a rate less than untreated tumor growth rate. Preferably, wherein the tumor growth rate is reduced for about 20% to about 100%.

Different therapeutically effective amounts may be applicable for different diseases and conditions, as will be readily known by those of ordinary skill in the art.  
20       Similarly, amounts sufficient to treat or prevent such disorders, but insufficient to cause adverse effects associated with compounds of Formula I, are also encompassed by dosage amounts and dose frequency schedules.

The compounds of the invention were tested to determine biological activity using an *in vitro* tubulin polymerization assay, cell cycle analysis, and SRB cytotoxicity assay.  
25       The results of the assays are summarized in Tables 1-5.

Briefly, tubulin polymerization is a kinetic process that is temperature-dependent and requires GTP and was performed as follows. Soluble tubulin dimers polymerize into microtubules upon warming, and polymerization *in vitro* correlates with an increase in turbidity (measured at 340 nm). Lyophilized bovine tubulin (HTS Tubulin - 97% tubulin,  
30       <3% MAPs - Cytoskeleton Inc.) was resuspended in G-PEM buffer (80 mM PIPES pH 7, 1 mM EGTA, 1 mM MgCl<sub>2</sub>, 1 mM GTP, 5% glycerol) to a final concentration of 3 mg/ml and kept at 4°C. Compounds in 100x stock solutions in DMSO were dotted to pre-warmed 96-well plates (Corning Costar 3696), the plates were transferred to a 37°C plate reader (SPECTRAmax Plus, Molecular Devices), cold tubulin was added to the wells,

and the plates were shaken for mixing. The absorbance at 340 nm was determined at one minute intervals for 30 minutes. Kinetic curves with 30 points each were collected for each compound, and the dynamic range was between 0 and 0.4 OD units. The percentage inhibition values were calculated using the 30 minute data point and based on control samples (treated with 1% DMSO only). The assay is a modified version of the HTS kit sold by Cytoskeleton (1830 S. Acoma St., Denver, Colorado), adapted to maximize throughput and reduce time, without reduction in dynamic range or sensitivity, while retaining the ability to detect compounds that inhibit or enhance tubulin polymerization.

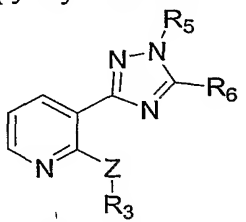

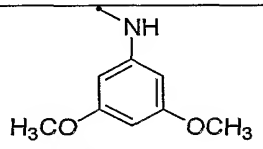

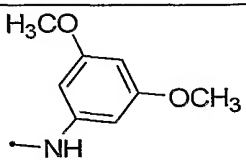

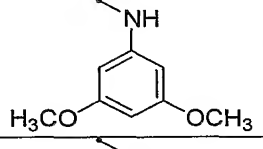

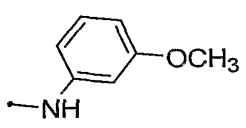

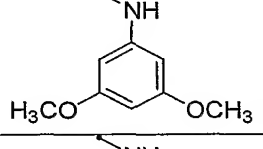

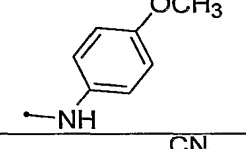

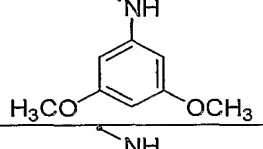

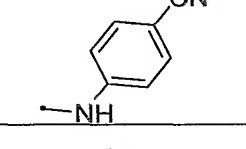

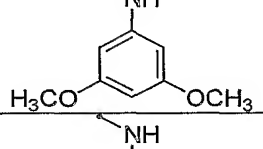

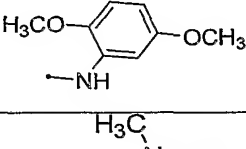

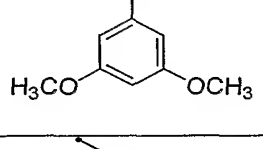

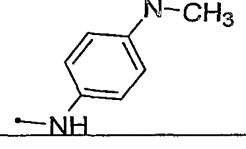

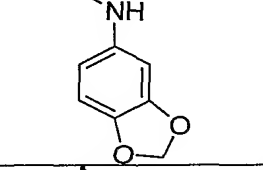

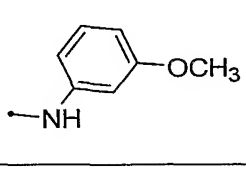

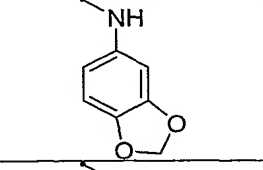

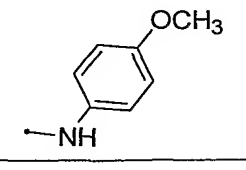

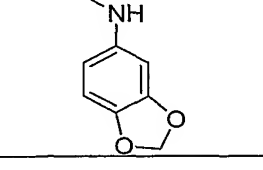

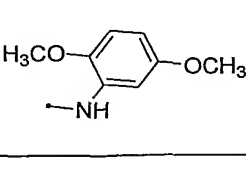

The cell cycle analysis was performed as follows. Cancer cells (A431, human epidermoid carcinoma cells) were maintained in culture in D-MEM media with 10% FBS and 1 mg/ml glutamate. Prior to experiment, cells were plated onto 6-well plates for a final density of 500,000 cells/well at the time of treatment. Cells were treated with the compounds of the invention at a concentration of about 0.01 to 1  $\mu$ M final concentrations (final 0.1% DMSO) for 24 hours, then trypsinized, collected, rinsed in PBS (phosphate buffered saline), and fixed in 70% cold ethanol overnight at 4°C. The cells were then rinsed with PBS, resuspended in PBS with 0.2% Tween, RNase was added (final 1  $\mu$ g/ml), cells were incubated at 37°C for 15 min, followed by addition of Propidium Iodide (final 50  $\mu$ g/ml), and a 30 minute incubation at room temperature. DNA ploidy was analyzed using flow cytometers (Epics Excel, Beckman-Coulter, or Guava PCA-96, Guava Technologies) and mitotic arrest characterized by massive accumulation of cells in the G2/M phase of cell cycle.

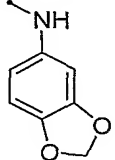

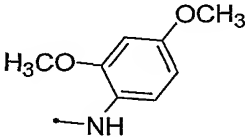

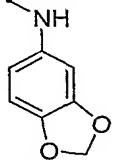

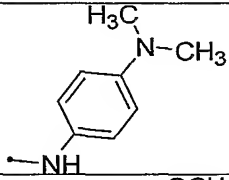

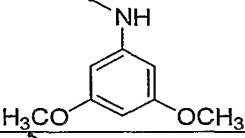

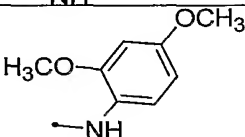

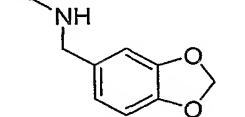

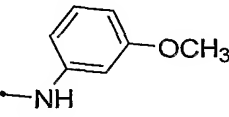

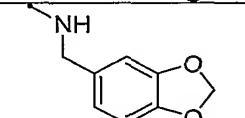

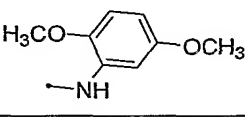

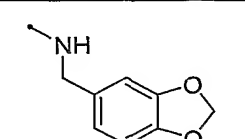

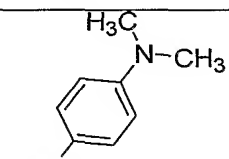

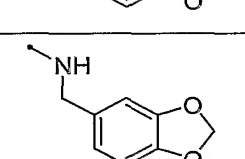

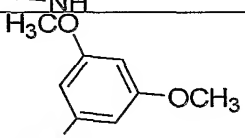

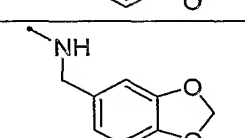

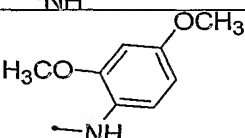

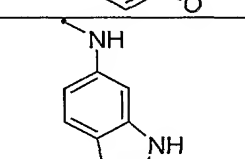

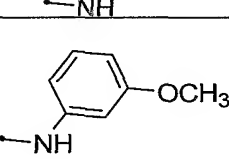

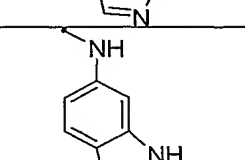

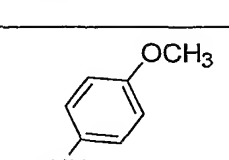

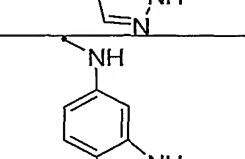

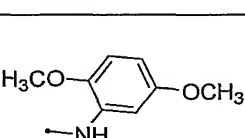

The in vitro growth inhibition activity of the compounds was determined by the Sulphorhodamine B assay. (Skehan P, Storeng R, Scudiero D, Monks A, McMahon J, Vistica D, Warren JT, Bokesch H, Kenney S, Boyd MR. New colorimetric cytotoxicity assay for anticancer-drug screening. *J Natl Cancer Inst* 82, 1107-1112, 1990).

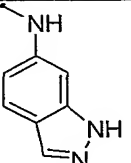

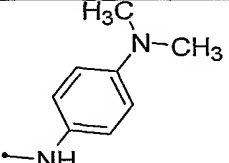

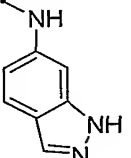

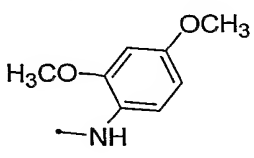

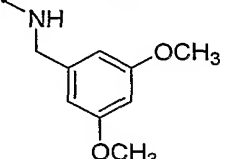

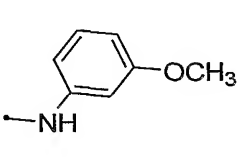

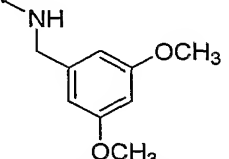

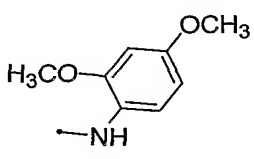

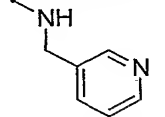

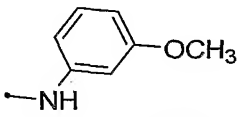

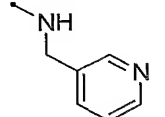

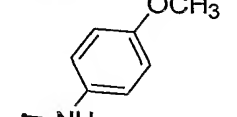

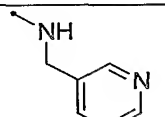

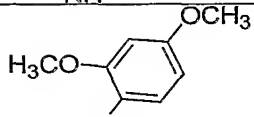

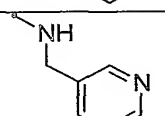

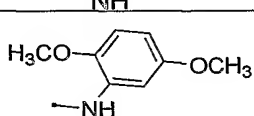

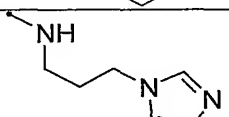

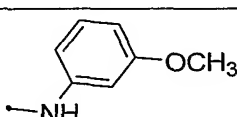

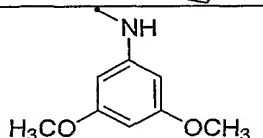

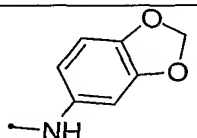

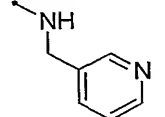

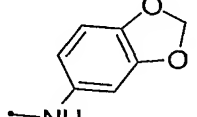

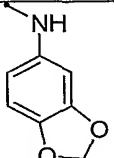

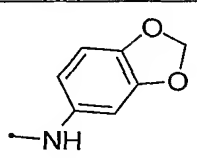

Sulphorhodamine B binds to basic amino acids and stains proteins which can be eluted and detected spectrophotometrically by measuring absorbance at 515 nm. The absorbance was indicative of the total protein content of the cells fixed to the walls of the plate well at a given time by trichloroacetic acid, which is a measure of the viable cell concentration.

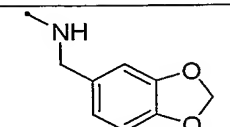

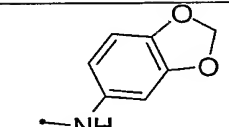

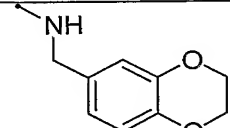

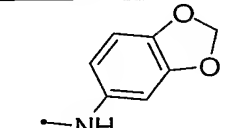

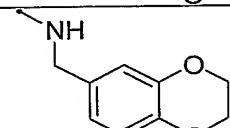

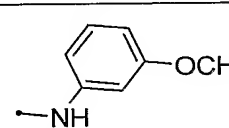

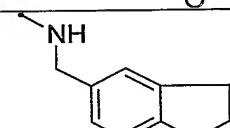

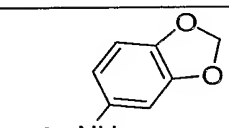

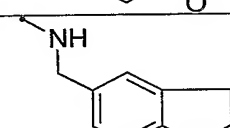

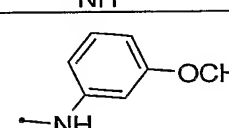

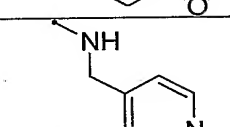

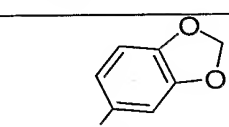

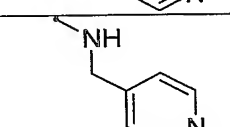

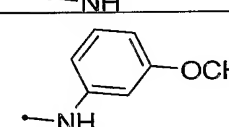

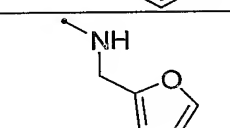

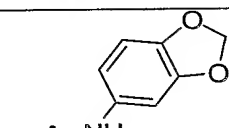

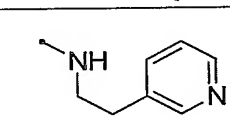

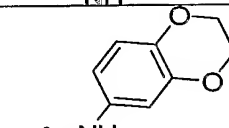

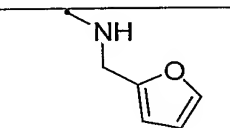

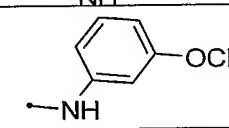

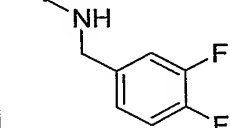

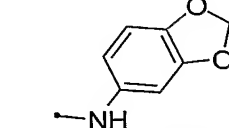

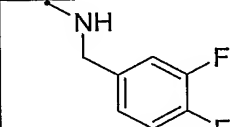

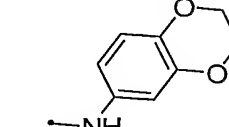

The results of the assays are included in the following tables.

Example 1: Synthesis of (3,5-Dimethoxy-phenyl)-{3-[5-(3,5-dimethoxy-phenylamino)-2H-[1,2,4]triazol-3-yl]-pyridin-2-yl}-amine (1)

Step 1: Synthesis of 2-chloro-nicotinic acid ethyl ester (1a):

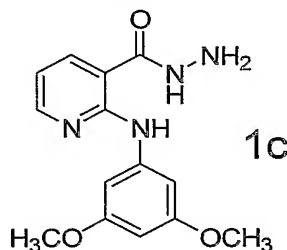

2-Chloropyridine-3-carboxylic acid (25 g, purchased from Aldrich) was refluxed in 200 ml of benzene and 150 ml of thionyl chloride over 3 hours. The solution was concentrated and chased with toluene. The residue obtained was refluxed in 100 ml of ethanol for 20 minutes. The solvents were removed in vacuum to give the product **1a**, as light yellow oil in 72% yield by weight. The product **1a** was identified by <sup>1</sup>HNMR and <sup>13</sup>CNMR. <sup>1</sup>HNMR (CDCl<sub>3</sub>) δ (ppm) 1.42 (t, J = 6.6 Hz, 3H), 4.43 (q, J = 6.8 Hz, 2H), 7.37 (br s, 1H), 8.18 (d, J = 6.6 Hz, 1H), 8.54 (s, 1H). <sup>13</sup>CNMR δ 13.8, 61.8, 122.0, 126.9, 140.0, 149.5, 151.4, 164.2.

After cooling to room temperature, the red solution deposited yellow solid that was filtered off and washed with 2-propanol. After drying in vacuum oven, the product **1c** appeared as yellow solid in 84% yield by weight. <sup>1</sup>HNMR (DMSO-d<sub>6</sub>) δ (ppm) 1.22 (br s, 2H), 4.00 (s, 6H), 6.18 (t, *J* = 2.2 Hz, 1H), 6.66–6.70 (m, 1H), 6.94 (s, 2H), 7.64 (dd, *J* = 7.7, 1.8 Hz, 1H), 7.70 (br s, 1H), 8.33 (dd, *J* = 4.8, 1.5 Hz, 1H), 10.1 (br s, 1H). <sup>13</sup>CNMR δ (ppm) 55.3, 94.8, 98.7, 100.2, 103.4, 100.4, 109.5, 113.1, 135.1, 141.5, 151.8, 160.9, 169.1.

10 Example 6: Synthesis of (3,5-Dimethoxy-phenyl)-{3-[5-(4-methanesulfonyl-phenyl)-4H-[1,2,4]triazol-3-yl]-pyridin-2-yl}-amine (**74**)

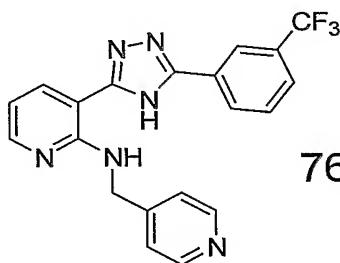

- Compound **74** was synthesized by heating a mixture of 2-(3,5-dimethoxy-phenylamino)-nicotinic acid hydrazide (**1c** from Example 1, 180 mg, 0.743 mmol), 4-methanesulfonylbenzamidinium hydrochloride (179.8 mg, 0.766 mmol, purchased from J&W Pharmed, PA), pyridine (2 ml) and triethylamine (0.15 ml) at 140°C for 12 hours. The reaction solution was poured into water (15 ml), and extracted three times with ethyl acetate (15 ml). The combined organic layer was washed with brine, and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. After filtration, the organic phase was evaporated, then the residue was washed with hot methanol to give 188 mg (53% yield) of product. <sup>1</sup>HNMR (DMSO-d<sub>6</sub>) δ (ppm)

Step 1: synthesis of (2,3-Dihydro-benzo[1,4]dioxin-6-yl)-[5-(2-nitro-phenyl)-4H-[1,2,4]triazol-3-yl]-amine (**127a**)

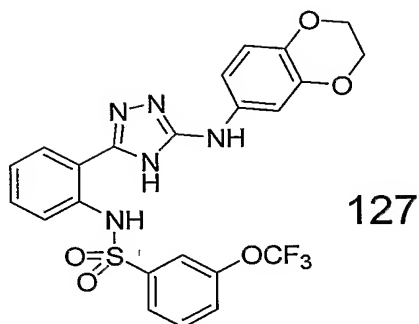

The reaction mixture of 2-nitrobenzoic hydrazide (1.0 g, 5.5 mmol, purchased from Aldrich) and 1-(2,3-dihydro-benzo[1,4]dioxin-6-yl)-2-methyl-isothiourea (2.34 g, 6.6 mmol, from Oakwood Products, Inc.) in pyridine (10 ml) was stirred at 130°C under argon for 12 hours. The reaction was cooled down to room temperature and poured into water 50 ml. After extracting with ethyl acetate (40 ml X 3), the combined organic layer was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. After filtration and evaporation, the organic residue was purified by silica gel column (hexane:ethyl acetate = 3:1). Compound **127a** recovered as 1.6 g white solid in 85.8% yield. <sup>1</sup>HNMR (DMSO-d<sub>6</sub>) δ (ppm) 9.31 (s, 1H), 7.60-7.98 (m, 4H), 7.12 (s, 1H), 6.90-6.93 (m, 1H), 6.69-6.73 (m, 1H), 4.15-4.22 (m, 4H).

Step 2- synthesis of [5-(2-amino-phenyl)-4H-[1,2,4]triazol-3-yl]-(2,3-dihydro-benzo[1,4]dioxin-6-yl)-amine (**127b**) 091675

Triazole nitro compound **127a** (1.6 g), ethanol (120 ml), and 10%Pd-C (240 mg) was added into a flask. The reaction mixture was degassed, and placed under hydrogen. The reaction mixture stirred at 60°C for 4 hours. After filtration of catalyst, the colorless solution was evaporated to obtained **127b** as a white solid 1.2 g (yield 82.1%). <sup>1</sup>HNMR (DMSO-d<sub>6</sub>) δ (ppm) 13.20 (s, 1H), 9.04 (s, 1H), 7.82 (s, 1H), 7.31 (d, 1H), 7.15-7.20 (m, 1H), 6.97-7.00 (m, 1H), 6.60-6.78 (m, 4H), 4.20-4.28 (m, 4H).

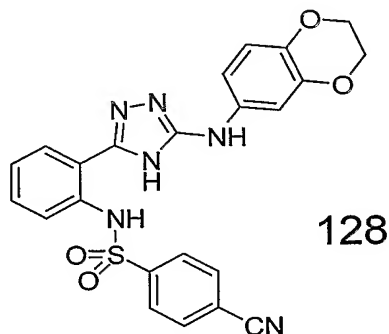

Step 3- synthesis of N-{2-[5-(2,3-Dihydro-benzo[1,4]dioxin-6-ylamino)-4H-[1,2,4]triazol-3-yl]-phenyl}-3-trifluoromethoxy-benzenesulfonamide (**127**)

To a solution of amine triazole compound **127b** (100 mg, 0.323 mmol) in pyridine (2 ml), 3-trifluoromethoxy-benzenesulfonyl chloride (109.5 mg, 0.42 mmol, purchased from Aldrich) was added. The reaction mixture was stirred at ambient temperature under argon for 12 hours. The reaction was quenched with saturated NaHCO<sub>3</sub>. After adding additional 20 ml of water, the mixture was extracted with ethyl acetate (20 ml X 3). The combined organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>. After filtration and evaporation, CH<sub>2</sub>Cl<sub>2</sub> was added to the organic resulting organic residue and a solid precipitated. The solid was separated from solvent by filtration to obtain 52 mg of **127** in 30% yield. <sup>1</sup>HNMR (DMSO-d<sub>6</sub>) δ (ppm) 8.64-8.68 (m, 2H), 7.85-8.06 (m, 4H), 7.64-7.66 (m, 1H), 7.40-7.46 (m, 2H), 7.12-7.38 (m, 2H), 6.82-6.85 (m, 1H), 4.20-4.28 (m, 4H). Example 15: synthesis of (4-Fluoro-benzyl)-{3-[5-(4-methanesulfonyl-phenyl)-[1,3,4]oxadiazol-2-yl]-pyridin-2-yl}-amine (212)

Step 1: synthesis of 2-(4-fluoro-benzylamino)-nicotinic acid ethyl ester (212a)

Ethyl-2-chloronicotinate (1.5 ml, 10.4 mmol) was added to a solution of triethylamine (3.5 ml, 24.9 mmol) in dimethylsulfoxide (7 ml) and stirred for five minutes. 4-Fluorobenzylamine (1.5 ml, 13.1 mmol) was added to the mixture and heated to 70°C. Upon disappearance of starting material, the reaction mixture was diluted with ethyl acetate (20 ml) and washed with deionized water (2 x 20 ml). The aqueous wash was re-extracted with ethyl acetate (3 x 20 ml). The organic layers were combined and dried over anhydrous sodium sulfate. The sodium sulfate was filtered, and the organic solvent was removed *in vacuo*. The yellow oil was purified with silica gel flash column chromatography (Hexane: Dichloromethane → 1:2) to yield a yellow oil (2.0 g, 71%).

Isopropyl alcohol (10 ml) was added to a round bottom flask containing intermediate 212a (1.75g, 6.38 mmol). Hydrazine monohydrate (3 ml, 61.8 mmol) was added to the mixture and heated to 70°C. Upon disappearance of starting material, the reaction mixture was diluted with ethyl acetate (15 ml) and washed with deionized water (2 X 15 ml). The organic layer was dried over anhydrous sodium sulfate and filtered. The organic solvent was removed *in vacuo* to yield a yellow oil. The flask was placed in an ice water bath, and the white solid was filtered and washed with diethyl ether (3 x 15 ml). Upon completion, the reaction was diluted with methylene chloride and washed 3x 10 ml 5% citric acid, 3x 10 ml saturated aqueous sodium bicarbonate, and 3x 10 ml of saturated aqueous sodium chloride. The organic phase was dried over anhydrous magnesium sulfate, then filtered and concentrated.
- Methanol was added and the mixture was heated to 50°C. After 15 minutes, methanol was removed *in vacuo* to approximately 2 ml. A mixture of (2,3-dihydro-benzo[1,4]dioxin-6-yl)-[5-(2-hydroxy-phenyl)-oxazol-2-yl]-ammonium chloride (0.2 mmol, 69 mg) and 4-bromomethyl-pyridine hydrobromide (0.2 mmol, 51 mg, from Aldrich) in dry DMF (3 ml) was stirred at  $40^\circ\text{C}$  in the presence of  $\text{K}_2\text{CO}_3$  (1 mmol, 0.14 g). After 3 h, most of DMF was removed in vacuo. EtOAc and

H<sub>2</sub>O were added. The separated organic phase was washed with H<sub>2</sub>O, brine, and dried over Na<sub>2</sub>SO<sub>4</sub>. #### Example 22: In vitro tubulin polymerization assay

Tubulin polymerization is a kinetic process that is temperature-dependent and requires GTP. Soluble tubulin dimers polymerize into microtubules upon warming, and polymerization in vitro correlates with an increase in turbidity (measured at 340 nm). Liophilized bovine tubulin (HTS Tubulin - 97% tubulin, <3% MAPs- Cytoskeleton Inc.) was resuspended in G-PEM buffer (80 mM PIPES pH 7, 1 mM EGTA, 1 mM MgCl<sub>2</sub>, 1 mM GTP, 5% glycerol) to a final concentration of 3 mg/ml and kept at 4°C. Compounds in 100x stock solutions in DMSO were dotted to pre-warmed 96-well plates (Corning Costar 3696), the plates were immediately transferred to a 37°C plate reader (SPECTRAMax Plus, Molecular Devices), cold tubulin was added to the wells, plates were shaken for mixing, and absorbance at 340nm was read every minute for 30 minutes. Kinetic curves with 30 points each were collected for each compound, and the dynamic range was between 0 and 0.4 OD units. Percentage inhibition values were calculated using the 30 minute data point, based on control samples (treated with 1% DMSO only). This assay is a modified version of the HTS kit sold by Cytoskeleton, adapted to maximize throughput and reduce time, without reduction in dynamic range or sensitivity, while retaining the ability to detect compounds that inhibit or enhance tubulin polymerization.

#### Example 23: Cell cycle analysis

Cancer cells (A431, human epidermoid cells) were maintained in culture in D-MEM media with 10% FBS and 1 mg/ml glutamate. Prior to experiment, cells are plated onto 6-well plates for a final density of 500,000 cells/well at the time of treatment. Cells were treated with compounds at 0.01-1  $\mu$ M final concentrations (final 0.1% DMSO) for 24 hours, then trypsinized, collected, rinsed in PBS (phosphate buffered saline), and fixed in 70% cold ethanol overnight at 4°C. Cells were then rinsed with PBS, resuspended in PBS with 0.2% Tween, RNase was added (final 1  $\mu$ g/ml), cells were incubated at 37°C for 15 min, followed by addition of Propidium Iodide (final 50  $\mu$ g/ml), and a 30 minute incubation at room temperature. DNA ploidy was analyzed using cell sorters (Epics Excel, Beckman-Coulter, or Guava PCA-96, Guava Technologies) and mitotic arrest characterized by massive accumulation of cells in the G2/M phase of cell cycle.

#### Example 24:

The in vitro growth inhibition activity of the compounds was determined using a Sulphorhodamine B assay. See, Skehan *et al.*, "New colorimetric cytotoxicity assay for anticancer-drug screening," *J. Natl. Cancer Inst.*, 82, 1107-1112, (1990).

Sulphorhodamine B binds to basic amino acids and stains proteins which can be eluted and detected spectrophotometrically by measuring absorbance at 515 nm. The absorbance indicates the total protein content of the cells fixed to the walls of the plate well at a given time by trichloroacetic acid, which is a measure of the viable cell concentration.

The reagents used in the assay can be purchased from commercial sources and include Sulphorhodamine B 0.4%(w/v) in 1%(v/v) acetic acid (Sigma Cat#S-1402); trichloroacetic acid 50% (w/v) in deionized water, working solution (Sigma Cat#T-9159); and trizma base (Tris) 10 mM working solution, pH 7.5 (Sigma Cat#T-7693).

The procedure was carried out over four days. In Day 1, the cells were seeded in a seed 10,000 cells/100  $\mu$ L/well in 96 well plate in duplicates as per template. Also, seed cells in extra plate for time zero (To plate). Thereafter, the cells were incubated for 24 hours at 37°C with 5% CO<sub>2</sub>.

On Day 2, the test compound was added to the cells at five log doses from 100  $\mu$ M to 0.01  $\mu$ M (Volume of addition =100  $\mu$ L in 1% DMSO for all compound concentrations, Control treatment = 1% DMSO).

The compounds were prepared by weighing the test compounds in 1.5 ml eppendorf tubes and calculating the volume of DMSO to be added to bring the

concentration of the compound to 20 mM. Thereafter, a 20 mM stock was made and diluted by four 10 fold dilutions in DMSO to get 2, 0.2, 0.02 and 0.002 mM solutions. Each solution was diluted 100 times (10  $\mu$ L to 1 ml medium) and a further addition to the culture plate (100  $\mu$ L) to half the concentration of cells was made. The final well concentration for 20 mM stock was 100  $\mu$ M and similarly with other test concentrations.

The cells were incubated for 48 hours at 37°C with 5% CO<sub>2</sub> and terminated by adding 50  $\mu$ L of 50% cold trichloroacetic acid (10% to final). Thereafter, the cells were incubated for one hour at 4°C.

On Day 4, the cells were fixed to the wells by the addition of 50  $\mu$ L of 50% cold trichloroacetic acid (10% to final) and incubated for 1 hour at 4°C. The supernatant was discarded by force inverting the plate into the sink followed by washing thrice with tap water and the plates are then air-dried. 100  $\mu$ L SRB (0.4 % in 1 % acetic acid) was added to each well and the plates were incubated for 10 minutes at room temperature. Unbound dye was removed by force inverting the plate into the sink and washing thrice with 1 % acetic acid. Thereafter, the plates were allowed to air dry.

Bound SRB was solubilized with 100  $\mu$ L of 10 mM Tris, pH 7.4 and the absorbance was measured at a wavelength of 515 nm.

A sample set of calculations was performed as follows. The percentage growth was calculated by  $T - T_0 / C - T_0 \times 100$  if  $T > T_0$  and  $T - T_0 / T_0 \times 100$  if  $T < T_0$ , wherein T is Test OD (with compound), C is Control OD,  $T_0$  is Time Zero OD (cell growth at the time of drug addition). A plot was made with concentrations on X axis and percentage growth on Y axis, the intercept at 50 on the scale gave the GI50 (growth inhibition to 50%) values.

GI50 stands for the concentration of compound required to inhibit 50% tumor cell growth. The in vitro growth inhibition activities of the compounds were determined in A431 human cancer cell line.
